I am looking for these two architecture-oriented features : High parallelism ( $N^2$ ) vs. low latency ( $N^3$ ) In-memory computing ( $N^2$ ) vs. fast access to global memory So, any pointer or reference to research paper will be appreciated. Thanks in advance! A: You should be able to find these results in the literature. The GPGPU softwares usually have many high-level units that increase peak performance (e.g. general matrix-vector multiplication) and that can be optimized differently, giving it high peak performance. In the competition between GPGPU and traditional computing architectures, it is usually considered that GPGPU get higher performance in total (peak performance plus low latency) and that GPGPU have a much higher power consumption. A: When comparing apples-to-apples, GPUs are the superior platform for most of what the supercomputers do. Here are some links for you to explore: In general, a good GPG
