Clark, PhD 1. Introduction The completion of the human genome sequence in 2003 and the decade-long epidemic of popular and government-sponsored sequencing of microbial genomes during the same period have fundamentally changed the way biologists think about genetics. From the analyses of these genomes we are now also beginning to understand mechanisms of genetic instability that give rise to cancer. Such knowledge is of great importance to medicine as both the incidence and mortality of cancer continue to increase. The incredible progress and magnitude of these advances in technology have had the effect of creating a false impression that all aspects of biology can be conquered by the application of this new technology. This impression has created a situation where the impact of even minor modifications of existing technologies is considered to be limited. It may also mean that the current generation of students entering the research academy does not understand the complexity of the science they will be entering to learn. Neither these students nor their mentors have a concept of what it means for new technologies to be based on the existing technologies rather than entirely new. With the exception of a few groups, the technique of DNA sequencing has been stable for the past 20 years. The commercially available benchtop sequencers have also been very stable for this period. The industrialization of this field also meant that it had gained a certain amount of inertia. This has led to the relegation of the analysis of RNA to certain niche groups with specialized expertise. This has created a situation where it is now very difficult to get a researcher working on any other aspect of RNA analysis to even consider anything not based on the current technologies. Consequently, these other approaches are not being used by most researchers because they are unaware of them. There is one exception to this

The epidermal permeability barrier is a complex multi-component system that tightly controls the influx of water, solutes, chemicals, microorganisms, and the ensuing toxic insult to the stratum corneum while at the same time maintaining the essential mechanisms of water excretion. This article examines the molecular basis of the epidermal permeability barrier, focusing on the keratins, the lipid transporters, the dermal proteins, and the epidermal lipid structure and organization.
